

KNOWLEDGE ARTICLE

Slow Laptop, Freezing, and High Resource Usage

Intent key	SlowLaptopPerformance	Category	Device Performance
Routing	Bedrock Knowledge Base / LLM fallback	Lex overlap	No direct match in the supplied intent workbook

Purpose and intent scope

Use this article when a managed laptop is unusually slow, freezes, takes a long time to start, has high CPU or memory use, or applications become unresponsive.

Suggested answer

Save your work and restart the laptop first. Close unused applications and browser tabs, check available disk space, and use the system task manager to identify unusually high CPU, memory, or disk usage. Allow approved updates to finish and keep the device ventilated. Do not disable security tools or install cleanup utilities. Escalate immediately if the device overheats, crashes repeatedly, or fails to start.

Common user utterances

- My laptop is very slow.
- The computer keeps freezing.
- Applications take a long time to open.
- CPU usage is always high.
- The laptop became slow after an update.
- The fan is constantly running.
- My device takes a long time to start.
- The browser and Teams are using too much memory.

Recommended troubleshooting sequence

1. Save open work and restart the device. A restart clears stalled processes and completes pending updates.
2. Close unused browser tabs and applications, especially multiple meeting, development, or media applications.
3. Check available disk space. Keep sufficient free space for updates, temporary files, and normal system operation.
4. Open the system task manager and identify applications with unusually high CPU, memory, or disk usage. Record the application name before closing it.
5. Allow approved operating-system and application updates to complete, then restart when prompted.
6. Disconnect unnecessary external devices and test again.
7. Make sure the device is on a hard, ventilated surface and that air vents are not blocked.
8. If performance problems began after installing unapproved software or browser extensions, stop using them and contact support.

Security and safety boundaries

Do not recommend the following actions:

- Do not disable antivirus, endpoint protection, encryption, or device-management services.
- Do not use registry cleaners, driver-updater utilities, or unapproved optimization tools.
- Do not terminate unfamiliar security or system processes.

When to escalate

- The device repeatedly crashes, shows a blue screen, or fails to start.
- Disk usage remains near 100 percent after a restart.
- The device is extremely hot, swollen, damaged, or produces an unusual smell.
- Performance remains poor with all nonessential applications closed.
- The issue affects multiple managed devices after the same update.

Information to collect for support

- When the slowdown started
- Applications affected
- CPU, memory, and disk usage observations
- Available disk space
- Recent updates or software changes
- Any crash message or error code

Routing guidance for the assistant

Use this article when the request clearly matches the intent scope. Provide the suggested answer, then guide the user through the troubleshooting steps in order. Ask only for non-sensitive diagnostic details. If an escalation condition is met, recommend creating a support request and include the collected details. Never request passwords, MFA codes, private keys, or security tokens.

Knowledge-base note

This article was intentionally created for a topic not directly represented in the supplied Lex intent list. It is suitable for retrieval by an LLM fallback or Amazon Bedrock Knowledge Base. Internal service-desk URLs, approved software names, and organization-specific escalation paths should be added only after validation.
